

May's Orders – AWS

Official Release Dossier

Release v0.4.0

Technical checkpoint: **week-4-final-20260914**

Commit: **6a34a02**

Maker / Creator: Maymilly Nowak

Serverless Order & Processing Foundation for the Mays Recruiting Intelligence
System

Status: **GREEN** · Phase 2 technically verified

1. Release Overview

May's Orders – AWS is a generic, serverless Orders & Processing platform. It provides a controlled foundation for asynchronous order processing and is designed to remain independent from recruiting-domain intelligence such as ATS, CV matching, job search and agent-specific business logic.

This release documents the verified Phase-2 checkpoint. It is a stable technical milestone, not a declaration that the project will no longer evolve. Future development is expected to continue independently and through controlled changes after the immutable technical checkpoint.

Release facts

Release	v0.4.0
Technical checkpoint	week-4-final-20260914
Commit	6a34a02b371b24c40a9557f93ceb8bf735b88b07
Verified flow	Producer → SQS → Worker → DynamoDB
Verified state transition	PENDING → CONFIRMED
Maker / Creator	Maymilly Nowak

2. Current Architecture

The verified architecture is deliberately simple and serverless:

Client	↓	Cognito / JWT
Cognito / JWT	↓	API Gateway
API Gateway	AWS_PROXY	Producer Lambda
Producer Lambda	■■	DynamoDB: PutItem (PENDING)
Producer Lambda	■■	SQS: SendMessage
SQS	↓	Worker Lambda
Worker Lambda	↓	DynamoDB: UpdateItem (CONFIRMED)

Important: API Gateway remains an AWS_PROXY integration to the producer Lambda. There is no direct API Gateway → SQS integration in this checkpoint.

3. Phase-2 End-to-End Verification

The decisive verification was not limited to observing log messages. The test was followed through to the actual persisted DynamoDB state.

1	Order request	Producer receives request
2	DynamoDB	Order created with status PENDING
3	SQS	Producer sends order message
4	Worker	Worker receives and processes message
5	DynamoDB	Worker updates status to CONFIRMED
6	E2E result	PENDING → CONFIRMED verified in persistence

4. Root Cause → Solution

The Phase-2 persistence failure was traced to IAM governance rather than to SQS timing or DynamoDB consistency.

Root cause	Observed issue
Wrong account ID in Permissions Boundary	20571105849 was used instead of the correct 240571105849.
Missing worker permission	Worker policy lacked dynamodb:UpdateItem.

Correction	Result
Permissions Boundary account ID corrected	DynamoDB access was no longer blocked by the boundary.
dynamodb:UpdateItem added to worker IAM policy	Worker could persist the CONFIRMED state.
Real E2E verification repeated	PENDING → CONFIRMED was verified in DynamoDB.

5. Security, Governance & Engineering Lessons

The checkpoint reinforces several engineering principles:

- IAM policies must always be evaluated together with Permissions Boundaries.
- CloudWatch logs can prove that processing occurred, but do not by themselves prove persistent state.
- End-to-end verification must reach the actual persistence layer.
- The generic Orders platform and recruiting-domain intelligence should remain separated by an explicit integration boundary.
- The technical tag is an immutable checkpoint; subsequent documentation or feature work must not rewrite that checkpoint.

6. Mays Recruiting Intelligence Integration

The intended architecture separates the recruiting system's Agent Runtime from the generic Orders platform. A development adapter can bridge the runtime today; a future **RealMaysOrdersAdapter** can be introduced after the external integration contract is jointly defined and verified.

Mays-Orders-AWS does not host the recruiting agents. Domain intelligence remains in the Agent Runtime and its domain agents. The Orders platform remains responsible for generic order/processing lifecycle, AWS/Terraform/IAM governance, operations and the agreed integration contract.

7. Maker / Creator

Maker / Creator: Maymilly Nowak

The Maker identity is intentionally distinct from a Git hosting account, Git author/committer identity or technical AWS identity. The release dossier therefore uses the creator name **Maymilly Nowak** and does not substitute a GitHub username or the shortened form “May Nowak”.

Books by Maymilly Nowak

- **Die Kleine und das Universum** — published by epubli in 2020.
- **Der Stamm in den Kronen** — published by epubli; current catalog records include later editions.

The bibliographic information above was checked against current public publisher/catalog records. The release dossier treats these books as part of the creator identity, not as technical dependencies of May's Orders.

Creator references: epubli author catalog and book records; Google Books / Apple Books records for “Die Kleine und das Universum”.

8. AI-Assisted Engineering

The project was developed with human-led engineering and AI/model assistance. AI support was used as an engineering accelerator across analysis, implementation support, test generation, debugging, documentation, review and recovery of working context. Technical decisions, verification and release authority remain with the project owner and the engineering workflow.

9. Education & Practical Cloud-Native Learning

The project serves as practical cloud-native engineering work alongside DCI/AWS-oriented learning. This dossier deliberately avoids inventing certification names, dates or program details that are not explicitly established in the release source material.

10. Scope & Roadmap

Current verified scope

- Serverless order intake through API Gateway and Lambda.
- Authenticated access boundary using Cognito/JWT.
- DynamoDB order persistence.
- Asynchronous SQS processing.
- Worker-driven PENDING → CONFIRMED transition.
- Terraform/IAM governance and auditable technical checkpoint.

Future direction

- RealMaysOrdersAdapter and the jointly defined external integration contract.
- Further Agent Runtime integration.
- Additional lifecycle and reliability capabilities only after the current foundation is intentionally extended.

11. Official Checkpoint Statement

Phase 2 of the May's Orders AWS implementation is complete and technically verified.

Technical checkpoint: **week-4-final-20260914**

Commit: **6a34a02**

Verified flow: **Producer → SQS → Worker → DynamoDB CONFIRMED**

Release v0.4.0 documents this milestone as a stable checkpoint while keeping the project open for controlled future development.
